The viruses in the subfamily Parvovirinae only infect vertebrates and may cause disease in human (Qiu et al., 2017). The most well-known human pathogen in this subfamily of viruses is parvovirus B19, a member of the genus Erythroparvovirus (Heegaard and Brown, 2002).

Introduction. The viruses from the proposed order Megavirales have been described infecting eukaryotic hosts from different taxa (Colson et al., 2012). Although giant viruses of phagocytic protists may infect a wide variety of hosts, each species apparently has host specificity (Colson

In the early stages of invertebrate pathology, research techniques included those used in traditional virology, bacteriology, mycology, nematology and entomology to better understand the interactions between the target organisms and their entomopathogens.
