## **Aircraft Lateral Stability Analysis**

Stability and control analysis is an important discipline to consider when designing an aircraft. An appropriate analysis can overcome deficiencies enforced by others disciplines, such as aerodynamics and loads. The efficiency of the control surfaces can also be maximized by a proper analysis.

## **MODERN METHODS OF AIRCRAFT STABILITY AND CONTROL ANALYSIS**

A mathematical analysis of the longitudinal static stability of a complete aircraft (including horizontal stabilizer) yields the position of center of gravity at which stability is neutral. This position is called the neutral point. (The larger the area of the horizontal stabilizer, and the greater the moment arm of the horizontal stabilizer about the aerodynamic center, the further aft is the neutral point.)

Lateral Stability Derivatives • A key to understanding the lateral dynamics is roll-yaw coupling. •  $L_p$  rolling moment due to roll rate: – Roll rate  $p$  causes right to move wing down, left wing to move up → Vertical velocity distribution over the wing  $W = py$  – Leads to a spanwise change in the AOA:  $\alpha_r(y) = py/U$

An aircraft with positive lateral stability rolls away from the sideslip (velocity vector) that results when a wing drops, and that usually means back toward level flight (although an aircraft with dihedral effect can go into a spiral dive if the bank angle is high and other moments prevail).

Lateral - Directional Oscillation. This motion exists in any airplane for which the ratio of static directional stability and dihedral effect lies between the limiting conditions for spiral divergences and directional divergence.

## **Longitudinal & Lateral Airplane Dynamics**

By lateral stability we are referring to the stability of the aircraft when rolling one wing down/one wing up, and vice versa. As an aircraft rolls and the wings are no longer perpendicular to the direction of gravitational acceleration, the lift force, which acts perpendicular to the surface of the wings, is also no longer parallel with gravity.

The analysis of flight motions is simplified, at least for small perturbations from certain equilibrium states, by the bi-lateral symmetry of most flight vehicles. This symmetry allows us to decompose motions into those involving longitudinal perturbations and those involving lateral/directional per-turbations.
