If the land surface is relatively steep, this pattern is retained until it is destroyed by rock falls or rock slides. If the land surface slopes more gently, the pattern can change to a hexagonal one (with "Y" junctions) as the rock surface is slowly lowered by erosion.

Earth Surface Processes and Landforms

Landforms on Earth. Any natural feature of the solid surface of the earth or any other planetary body is a landform. Usually, they are in the form of hills, mountains, plains, valleys, plateaus, canyons, shorelines, volcanoes, etc. Physical attributes such as elevation, slope, orientation, stratification, rock exposure, and soil type decided the characteristics of a landform.

Landforms on Earth and External Processes: Concepts ...

A landform is a feature on the Earth's surface that is part of the terrain. Mountains, hills, plateaus, and plains are the four major types of landforms. Minor landforms include buttes, canyons, valleys, and basins. Tectonic plate movement under the Earth can create landforms by pushing up mountains and hills.

An exposed soil surface is subject to two primary surface erosion processes: rainsplash and the shear stress of overland flow. Rainsplash energy is a function of precipitation intensity as well as the size and terminal velocity of the raindrops (Wischmeier and Smith, 1958; Carter et al., 1974). Flow hydraulics determine the shear stress of overland

British Society for Geomorphology - Wikipedia

Geomorphology is the study of the earth's landforms and the processes that made the landscape look the way it does today. What we see when we look at a scenic view is the result of the interplay of the forces that shape the earth's surface. These operate on many different timescales and involve geological as well as climatic forces.
