A turbocharger is basically a combination of a compressor and a turbine, both mounted on a common shaft. Turbocharger uses the exhaust gases of the engine itself, to rotate the turbine which in turn moves the compressor. Mainly two type of compressors are used in a turbocharger.

Turbocharger design: Construction and working of ...

A turbocharger, colloquially known as a turbo, is a turbine-driven, forced induction device that increases an internal combustion engine's efficiency and power output by forcing extra compressed air into the combustion chamber. This improvement over a naturally aspirated engine's power output is because the compressor can force more air—and proportionately more fuel—into the combustion ...

Turbocharger - Wikipedia

The operating principle of the turbocharger is based on the principle of momentum conservation. Part of the enthalpy (energy) of the exhaust gases is converted by the turbine into mechanical energy used to drive the compressor. The rotation of the compressor will draw air from the atmosphere and compress it before going into the engine.

All existing turbocharger units still undergo testing using guidelines, by the ASME and SAE societies. We will bypass the explanations of the Test stand parameters, cause they are irrelevant to the theory we are here to explain. Below is just one version of a test stand, which is usually referred to as the (Loop Hot gas stand).

Turbo Engineering Explained

Turbocharging is the most commonly used supercharging technology by internal combustion engines (ICE) for forced intake air induction. With turbocharging, the exhaust-gas energy is used to increase the inlet air density. Turbocharging is seen as the oldest heat recovery technology used in internal combustion engines.
