Gas lift is a method of artificial lift that uses an external source of high-pressure gas for supplementing formation gas to lift the well fluids. The principle of gas lift is that gas injected into the tubing reduces the density of the fluids in the tubing, and the bubbles have a “scrubbing” action on the liquids.

There is therefore a very significant potential for production increase by understanding the principles of Gas Lift and this is a huge opportunity for any engineer willing to master this activation method. This class will present you the different forms of Gas Lift that you can find in the oil industry.

PRINCIPLES AND METHODS OF GAS LIFT The mechanism used in the earliest air lift application (1864 in Pennsylvania) was that of a two-pipe system, in which air was injected down one pipe and returned through the second pipe at a shallower depth. The air returned to the surface pushing some fluid ahead of it in the second pipe.

the high-pressure gas used for lift gas injection usually is provided by the discharge of a compressor (see Chapter 11: Gas lift). There is an optimum combination of wellhead pressure, gas lift injection pressure, gas lift injection rate, and compression requirements that can be found for any specific well.

The main goals in the design of a gas lift well are to find the depths, area ratios, and calibration pressures of the operating and unloading valves. The gas lift valve through which gas is injected during the normal operation of the well is called the “operating” valve and its depth is referred to as the “point of
